## Quick Review

## The general form of a synchronous sequential circuit

[ Figure 6.1 from the textbook]

## Moore Type

## Mealy Type

## Moore Machine

- The machine's current state and current inputs are used to decide which next state to transition into.
- The machine's current state decides the current output.

## Mealy Machine

- The machine's current state and current inputs are used to decide which next state to transition into.
- The machine's current state and current input values decide the current output.

## Example \#1

We need to find both the next state logic and the output logic implied by this machine.

## How to represent the States?

One way is to encode each state with a 2-bit binary number

$$
\begin{aligned}
& A \sim 00 \\
& B \sim 01 \\
& C \sim 10
\end{aligned}
$$

$$
\begin{aligned}
& A \sim 00 \\
& B \sim 01 \\
& C \sim 10
\end{aligned}
$$

How many flip-flops do we need?

## Let's use two flip flops <br> to hold the state of this machine

Clock

We will call $y_{1}$ and $y_{2}$ the present state variables.
We will call $Y_{1}$ and $Y_{2}$ the next state variables.
[ Figure 6.5 from the textbook ]

## Clock

Two zeros on the output JOINTLY represent state A.

Clock

This flip-flop output pattern represents state $B$.

Clock

This flip-flop output pattern represents state C.

Clock

What does this flip-flop output pattern represent?

Clock

This would be state D, but we don't have one in this example. So this is an impossible state.

We will call $y_{1}$ and $y_{2}$ the present state variables.
We will call $Y_{1}$ and $Y_{2}$ the next state variables.
[ Figure 6.5 from the textbook]

$$
Q(t+1)=Y_{2} Y_{1} \quad Q(t)=y_{2} y_{1}
$$

We will call $y_{1}$ and $y_{2}$ the present state variables.
We will call $Y_{1}$ and $Y_{2}$ the next state variables.
[ Figure 6.5 from the textbook]

We need to find logic expressions for $Y_{1}\left(w, y_{1}, y_{2}\right), Y_{2}\left(w, y_{1}, y_{2}\right)$, and $z\left(y_{1}, y_{2}\right)$.
[ Figure 6.5 from the textbook]

> We need to find logic expressions for $Y_{1}\left(w, y_{1}, y_{2}\right), Y_{2}\left(w, y_{1}, y_{2}\right)$, and $z\left(y_{1}, y_{2}\right)$.

| Present <br> state | Next state |  | Output |
| :---: | :---: | :---: | :---: |
|  | $w=0$ | $w=1$ |  |
| A | A | B | 0 |
| B | A | C | 0 |
| C | A | C | 1 |

Suppose that we encoded our states in the same order in which they were labeled:

$$
\begin{aligned}
& A \sim 00 \\
& B \sim 01 \\
& C \sim 10
\end{aligned}
$$

| Present <br> state | Next state |  | Output |

|  | $w=0$ | $w=1$ |  |
| A | A | B | 0 |
| B | A | C | 0 |
| C | A | C | 1 |

The finite state machine will
never reach a state encoded as 11.

## Don't care conditions simplify the combinatorial logic

Ignoring don't cares

$$
Y_{1}=w \bar{y}_{1} \bar{y}_{2}
$$

$$
Y_{2}=w y_{1} \bar{y}_{2}+\bar{w} y_{1} y_{2}
$$

$$
z=\bar{y}_{1} y_{2}
$$

Using don't cares

$$
Y_{1}=w \bar{y}_{1} \bar{y}_{2}
$$

$$
\begin{aligned}
Y_{2} & =w y_{1}+w y_{2} \\
& =w\left(y_{1}+y_{2}\right)
\end{aligned}
$$

$$
z=y_{2}
$$

## Main Idea

Different state assignments of the same Moore machine generally lead to different circuits.

Some may be better than others.

## Example \#2

## Register Swap Controller

[ Figure 6.10 from the textbook ]

## Register Swap Controller

Design a Moore machine control circuit for swapping the contents of registers R1 and R2 by using R3 as a temporary.

These are the original values of the 8-bit registers

For clarity, only inputs that are equal to 1 will be shown.

## Some Questions

- How many flip-flops are we going to use?
- How many logic expressions do we need to find?

| Present state | Next state |  | Outputs |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| A |  |  |  |  |  |  |  |  |  |
| B |  |  |  |  |  |  |  |  |  |
| C |  |  |  |  |  |  |  |  |  |
| D |  |  |  |  |  |  |  |  |  |

| Present <br> state | Next state |  | Outputs |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| A | A | B | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| C | D | D | 1 | 0 | 0 | 1 | 0 | 0 | 0 |
| D | A | A | 0 | 1 | 0 | 0 | 1 | 0 | 1 |

As we saw before, we can expect that some state encodings will be better than others.

We will consider three encoding schemes.

# Encoding \#1: $A=00, B=01, C=10, D=11$ 

(Uses Two Flip-Flops)

(One-Hot Encoding - Uses Four Flip-Flops)

## One-Hot State Encoding

- So far, we have been encoding states in a way that minimizes the number of flip-flops.
- But sometimes we can decrease the complexity of our logic if we encode states more sparsely.

## Encoding for State A

## Encoding for State $\mathbf{B}$

## Encoding for State C

## Let's Derive the Next-State Expressions

$$

We need to do four 5 -variable K-maps!
